

Agent Memory Layer

Persistent, private, searchable memory for production AI agents—without giving up control of your data.

PRIVATE scoped by default	TRACEABLE source-aware retrieval	SAFE production boundary	REPEATABLE idempotent refresh
------------------------------	-------------------------------------	-----------------------------	----------------------------------

The problem

Most agents forget, overreach, or retrieve without context.

Adding a vector database is not the same as building memory you can operate. The hard part is scope, promotion, provenance, refresh safety, and knowing what the agent actually used.

WHAT GALEOPS BUILDS	WHY IT MATTERS
Scoped durable memory	Searchable operating context
✓ Private, shared, and run-scoped context	✓ Wiki and code knowledge indexing
✓ Explicit promotion controls	✓ Source paths and locators
✓ Local-model compatible	✓ Duplicate-resistant identity
Safe operating layer	Business outcome
✓ Deterministic refreshes	✓ Agents stop starting from zero
✓ Before/after safety checks	✓ Teams can inspect the answer trail
✓ Read-only boundary around production memory	✓ Engineering can run the system with confidence

STARTING POINTS

Memory Readiness Audit	Agent Memory Foundation	Managed MemoryOps
\$1,500 one-time	\$4,500+ implementation	\$1,500+ / month
Map the agent stack, data flows, privacy boundaries, retrieval quality, and implementation path.	Deploy the PostgreSQL/pgvector memory layer, scoped access, Wiki/CodeGraph indexing, provenance, canaries, and handoff.	Monitor refreshes, tune retrieval, add sources, clean duplicates, and provide a monthly health report.

HOW IT WORKS

Map → Build → Verify → Operate

We start with the smallest safe deployment, prove isolation and refresh invariants in a canary, then leave your team with a system they can inspect and run.

Make memory an operating capability.
Bring your current agent workflow. We'll map the smallest safe path from "it forgets" to "we can run it."
